WO 01/75564 A2

(54) Title: **PLATFORM AND METHOD FOR REMOTE ATTESTATION OF A PLATFORM**

(57) Abstract: In one embodiment, a method of remote attestation for a special mode of operation. The method comprises storing an audit log within protected memory of a platform. The audit log is a listing of data representing each of a plurality of IsoX software modules loaded into the platform. The audit log is retrieved from the protected memory in response to receiving a remote attestation request from a remotely located platform. Then, the retrieved audit log is digitally signed to produce a digital signature for transfer to the remotely located platform.

PLATFORM AND METHOD FOR REMOTE ATTESTATION
OF A PLATFORM

BACKGROUND

1. **Field**

This invention relates to the field of platform security.

2. **Background**

Advances in microprocessor and communication technologies with a platform have opened up many opportunities for applications that go beyond the traditional ways of doing business. Electronic commerce (e-commerce) and business-to-business (B2B) transactions are now becoming popular, reaching the global markets at a fast rate. Unfortunately, while modern microprocessor technology provides users with convenient and efficient methods of doing business, communicating and transacting, this technology fails to support remote attestation. Remote attestation is a technique for ascertaining the operating state of a remotely located platform in a generally secure manner. By ascertaining the operating state of the platform prior to conducting e-commerce or B2B transactions with that platform, the user is imparted with greater confidence in the security of the transaction.

BRIEF DESCRIPTION OF THE DRAWINGS

The features and advantages of the present invention will become apparent from the following detailed description of the present invention in which:

Figure 1A is a diagram illustrating an embodiment of the logical operating architecture for the IsoX™ architecture of the platform.

Figure 1B is an illustrative diagram showing the accessibility of various elements in the operating system and the processor according to one embodiment of the invention.

Figure 1C is a first block diagram of an illustrative embodiment of a platform utilizing the present invention.

Figure 7 is a block diagram of an illustrative embodiment of a remote attestation unit employed in the removable token of Figure 1C to obtain a protected copy of the audit log.

DESCRIPTION

The present invention relates to a platform and method for remote attestation of a platform. Remote attestation may be conducted when the platform is operating in a special mode of operation. An example of this special mode includes a processor isolated execution "IsoX" mode as described below. More specifically, a processor executing in IsoX mode utilizes hardware-protected keying material that is cryptographically unique to produce a digital signature that includes information concerning the operating environment of the platform. The hardware that provides protection of the keying material, referred to herein as a "remote attestation unit" (RAU),

may be integrated in a core logic device (e.g., a processor or a chipset component) or a non-core logic device (e.g., token).

In the following description, certain terminology is used to discuss features of the present invention. For example, a "platform" includes components that perform different functions on stored information. Examples of a platform include, but are not limited or restricted to a computer (e.g., desktop, a laptop, a hand-held, a server, a workstation, etc.), desktop office equipment (e.g., printer, scanner, a facsimile machine, etc.), a wireless telephone handset, a television set-top box, and the like. Examples of a "component" include hardware (e.g., an integrated circuit, etc.) and/or one or more software modules. A "software module" is code that, when executed, performs a certain function. This code may include an operating system, an application, an applet or even a nub being a series of code instructions, possibly a subset of code from an applet. A "link" is broadly defined as one or more information-carrying mediums (e.g., electrical wire, optical fiber, cable, bus, or air in combination with wireless signaling technology) to establish a communication pathway. This pathway is deemed "protected" when it is virtually impossible to modify information routed over the pathway without detection.

In addition, the term "information" is defined as one or more bits of data, address, and/or control and a "segment" is one or more bytes of information. A "message" is a grouping of information, possibly packetized information. "Keying material" includes any information needed for a specific cryptographic algorithm such as a Digital Signature Algorithm. A "one-way function" is a function, mathematical or otherwise, that converts information from a variable-length to a fixed-length (referred to as a "hash value" or "digest"). The term "one-way" indicates that there does not readily exist an inverse function to recover any discernible portion of the original information from the fixed-length hash value. Examples of a hash function include MD5 provided by RSA Data Security of Redwood City, California, or Secure Hash Algorithm (SHA-1) as specified in a 1995 publication Secure Hash Standard FIPS 180-1 entitled "Federal Information Processing Standards Publication" (April 17, 1995).

I. Architecture Overview

In one embodiment, a platform utilizing the present invention may be configured with an isolated execution (IsoX™) architecture. The IsoX™ architecture includes logical and physical definitions of hardware and software components that interact directly or indirectly with an operating system of the platform. Herein, the operating system and a processor of the platform may have several levels of hierarchy, referred to as rings, which correspond to various operational modes. A "ring" is a logical division of hardware and software components that are designed to perform dedicated tasks within the platform. The division is typically based on the degree or level of privilege, namely the ability to make changes to the platform. For example, a ring-0 is the innermost ring, being at the highest level of the hierarchy. Ring-0 encompasses the most critical, privileged components. Ring-3 is the outermost ring, being at the lowest level of the hierarchy. Ring-3 typically encompasses user level applications, which are normally given the lowest level of privilege. Ring-1 and ring-2 represent the intermediate rings with decreasing levels of privilege.

Figure 1A is a diagram illustrating an embodiment of a logical operating architecture 50 of the IsoX™ architecture. The logical operating architecture 50 is an abstraction of the components of the operating system and processor. The logical operating architecture 50 includes ring-0 10, ring-1 20, ring-2 30, ring-3 40, and a processor nub loader 52. Each ring in the logical operating architecture 50 can operate in either (i) a normal execution mode or (ii) an IsoX mode. The processor nub loader 52 is an instance of a processor executive (PE) handler.

Ring-0 10 includes two portions: a normal execution Ring-0 11 and an isolated execution Ring-0 15. The normal execution Ring-0 11 includes software modules that are critical for the operating system, usually referred to as the "kernel". These software modules include a primary operating system 12 (e.g., kernel), software drivers 13, and hardware drivers 14. The isolated execution Ring-0 15 includes an operating system (OS) nub 16 and a processor nub 18 as described below. The OS nub 16 and the processor nub 18 are instances of an OS executive (OSE) and processor executive (PE), respectively. The OSE and the PE are part of executive entities that operate in a

protected environment associated with the isolated area 70 and the IsoX mode. The processor nub loader 52 is a bootstrap loader code that is responsible for loading the processor nub 18 from the processor or chipset into an isolated area as will be explained later.

Similarly, ring-1 20, ring-2 30, and ring-3 40 include normal execution ring-1 21, ring-2 31, ring-3 41, and isolated execution ring-1 25, ring-2 35, and ring-3 45, respectively. In particular, normal execution ring-3 includes N applications 42₁-42_N and isolated execution ring-3 includes M applets 46₁-46_M (where "N" and "M" are positive whole numbers).

One concept of the IsoX™ architecture is the creation of an isolated region in the system memory, which is protected by components of the platform (e.g., the processor and chipset). This isolated region, referred to herein as an "isolated area," may also be in cache memory that is protected by a translation look aside (TLB) access check. Access to this isolated area is permitted only from a front side bus (FSB) of the processor, using special bus cycles (referred to as "isolated read and write cycles") issued by the processor executing in IsoX mode.

It is contemplated that links dedicated to solely support special cycles during remote attestation (referred to as "attestation cycles") may be employed within the platform. These attestation cycles may be based on the isolated read and write cycles or may be independent from the isolated read and write cycles. In lieu of dedicated links, shared links may be employed within the platform to support remote attestation. Examples of these shared links include a Peripheral Component Interconnect (PCI) bus, an accelerated graphics port (AGP) bus, an Industry Standard Architecture (ISA) bus, a Universal Serial Bus (USB) bus and the like. The attestation cycles are issued to prove locality, namely that a device with the keying material and a signing engine is accessing information (e.g., an audit log) stored in protected memory within the platform. This mitigates the threat of software simulating the retrieval of the audit log for example.

The IsoX mode is initialized using a privileged instruction in the processor, combined with the processor nub loader 52. The processor nub loader 52 verifies and

loads a ring-0 nub software module (e.g., processor nub 18) into the isolated area. For security purposes, the processor nub loader 52 is non-modifiable, tamper-resistant and non-substitutable. In one embodiment, the processor nub loader 52 is implemented in read only memory (ROM).

One task of the processor nub 18 is to verify and load the ring-0 OS nub 16 into the isolated area. The OS nub 16 provides links to services in the primary operating system 12 (e.g., the unprotected segments of the operating system), provides page management within the isolated area, and has the responsibility for loading ring-3 application modules 45, including applets 46₁ to 46_M, into protected pages allocated in the isolated area. The OS nub 16 may also support paging of data between the isolated area and ordinary (e.g., non-isolated) memory. If so, then the OS nub 16 is also responsible for the integrity and confidentiality of the isolated area pages before evicting the page to the ordinary memory, and for checking the page contents upon restoration of the page.

Referring now to Figure 1B, a diagram of the illustrative elements associated with the operating system 10 and the processor for one embodiment of the invention is shown. For illustration purposes, only elements of ring-0 10 and ring-3 40 are shown. The various elements in the logical operating architecture 50 access an accessible physical memory 60 according to their ring hierarchy and the execution mode.

The accessible physical memory 60 includes an isolated area 70 and a non-isolated area 80. The isolated area 70 includes applet pages 72 and nub pages 74. The non-isolated area 80 includes application pages 82 and operating system pages 84. The isolated area 70 is accessible only to components of the operating system and processor operating in the IsoX mode. The non-isolated area 80 is accessible to all elements of the ring-0 operating system and processor.

The normal execution ring-0 11 including the primary OS 12, the software drivers 13, and the hardware drivers 14, can access both the OS pages 84 and the application pages 82. The normal execution ring-3, including applications 42₁ to 42_N, can access

only to the application pages 82. Both the normal execution ring-0 11 and ring-3 41, however, cannot access the isolated area 70.

The isolated execution ring-0 15, including the OS nub 16 and the processor nub 18, can access to both of the isolated area 70, including the applet pages 72 and the nub pages 74, and the non-isolated area 80, including the application pages 82 and the OS pages 84. The isolated execution ring-3 45, including applets 46₁ to 46_M, can access only to the application pages 82 and the applet pages 72. The applets 46₁ to 46_M reside in the isolated area 70.

Referring to Figure 1C, a block diagram of an illustrative embodiment of a platform utilizing the present invention is shown. In this embodiment, platform 100 comprises a processor 110, a chipset 120, a system memory 140 and peripheral components (e.g., tokens 180/182 coupled to a token link 185 and/or a token reader 190) in communication with each other. It is further contemplated that the platform 100 may contain optional components such as a non-volatile memory (e.g., flash) 160 and additional peripheral components. Examples of these additional peripheral components include, but are not limited or restricted to a mass storage device 170 and one or more input/output (I/O) devices 175. For clarity, the specific links for these peripheral components (e.g., PCI bus, AGP bus, ISA bus, USB bus, wireless transmitter/receiver combinations, etc.) are not shown.

In general, the processor 110 represents a central processing unit of any type of architecture, such as complex instruction set computers (CISC), reduced instruction set computers (RISC), very long instruction word (VLIW), or hybrid architecture. In one embodiment, the processor 110 includes multiple logical processors. A "logical processor," sometimes referred to as a thread, is a functional unit within a physical processor having an architectural state and physical resources allocated according to a specific partitioning functionality. Thus, a multi-threaded processor includes multiple logical processors. The processor 110 is compatible with the Intel Architecture (IA) processor, such as a PENTIUM® series, the IA-32™ and IA-64™. It will be appreciated by those skilled in the art that the basic description and operation of the processor 110 applies to either a single processor platform or a multi-processor platform.

The processor 110 may operate in a normal execution mode or an IsoX mode. In particular, an isolated execution circuit 115 provides a mechanism to allow the processor 110 to operate in an IsoX mode. The isolated execution circuit 115 provides hardware and software support for the IsoX mode. This support includes configuration for isolated execution, definition of the isolated area, definition (e.g., decoding and execution) of isolated instructions, generation of isolated access bus cycles, and generation of isolated mode interrupts. In one embodiment, as shown in Figure 3, the RAU may be implemented as part of the processor 110.

As shown in Figure 1C, a host link 116 is a front side bus that provides interface signals to allow the processor 110 to communicate with other processors or the chipset 120. In addition to normal mode, the host link 116 supports an isolated access link mode with corresponding interface signals for isolated read and write cycles when the processor 110 is configured in the IsoX mode. The isolated access link mode is asserted on memory accesses initiated while the processor 110 is in the IsoX mode if the physical address falls within the isolated area address range. The isolated access link mode is also asserted on instruction pre-fetch and cache write-back cycles if the address is within the isolated area address range. The processor 110 responds to snoop cycles to a cached address within the isolated area address range if the isolated access bus cycle is asserted.

Herein, the chipset 120 includes a memory control hub (MCH) 130 and an input/output control hub (ICH) 150 described below. The MCH 130 and the ICH 150 may be integrated into the same chip or placed in separate chips operating together. In another embodiment, as shown in Figure 4, the RAU may be implemented as part of the chipset 120.

With respect to the chipset 120, a MCH 130 provides control and configuration of memory and input/output devices such as the system memory 140 and the ICH 150. The MCH 130 provides interface circuits to recognize and service attestation cycles and/or isolated memory read and write cycles. In addition, the MCH 130 has memory range registers (e.g., base and length registers) to represent the isolated area in the system memory 140. Once configured, the MCH 130 aborts any access to the isolated area when the isolated access link mode is not asserted.

The system memory 140 stores code and data. The system memory 140 is typically implemented with dynamic random access memory (DRAM) or static random access memory (SRAM). The system memory 140 includes the accessible physical memory 60 (shown in Figure 1B). The accessible physical memory 60 includes the isolated area 70 and the non-isolated area 80 as shown in Figure 1B. The isolated area 70 is the memory area that is defined by the processor 110 when operating in the IsoX mode. Access to the isolated area 70 is restricted and is enforced by the processor 110 and/or the chipset 120 that integrates the isolated area functionality. The non-isolated area 80 includes a loaded operating system (OS). The loaded OS 142 is the portion of the operating system that is typically loaded from the mass storage device 170 via some boot code in a boot storage such as a boot read only memory (ROM). Of course, the system memory 140 may also include other programs or data which are not shown.

As shown in Figure 1C, the ICH 150 supports isolated execution in addition to traditional I/O functions. In this embodiment, the ICH 150 comprises at least the processor nub loader 52 (shown in Figure 1A), a hardware-protected memory 152, an isolated execution logical processing manager 154, and a token link interface 158. For clarity, only one ICH 150 is shown although platform 100 may be implemented with multiple ICHs. When there are multiple ICHs, a designated ICH is selected to control the isolated area configuration and status. This selection may be performed by an external strapping pin. As is known by one skilled in the art, other methods of selecting can be used.

The processor nub loader 52, as shown in Figures 1A and 1C, includes a processor nub loader code and its hash value (or digest). After being invoked by execution of an appropriated isolated instruction (e.g., ISO_INIT) by the processor 110, the processor nub loader 52 is transferred to the isolated area 70. Thereafter, the processor nub loader 52 copies the processor nub 18 from the non-volatile memory 160 into the isolated area 70, verifies and places a representation of the processor nub 18 (e.g., a hash value) into the protected memory 152. Herein, the protected memory 152 is implemented as a memory array with single write, multiple read capability. This non-modifiable capability is controlled by logic or is part of the inherent nature of the

memory itself. For example, as shown, the protected memory 152 may include a plurality of single write, multiple read registers.

As shown in Figures 1C and 2, the protected memory 152 is configured to support an audit log 156. An "audit log" 156 is information concerning the operating environment of the platform 100; namely, a listing of data that represents what information has been successfully loaded into the system memory 140 after power-on of the platform 100. For example, the representative data may be hash values of each software module loaded into the system memory 140. These software modules may include the processor nub 18, the OS nub 16, and/or any other critical software modules (e.g., ring-0 modules) loaded into the isolated area 70. Thus, the audit log 156 can act as a fingerprint that identifies information loaded into the platform (e.g., the ring-0 code controlling the isolated execution configuration and operation), and is used to attest or prove the state of the current isolated execution.

In another embodiment, both the protected memory 152 and unprotected memory (e.g., a memory array in the non-isolated area 80 of the system memory 140 of Figure 1C) may collectively provide a protected audit log 156. The audit log 156 is stored in the memory array while information concerning the state of the audit log 156 (e.g., a total hash value for the representative data within the audit log 156) is stored in the protected memory 152.

Referring still to Figure 1C, the non-volatile memory 160 stores non-volatile information. Typically, the non-volatile memory 160 is implemented in flash memory. The non-volatile memory 160 includes the processor nub 18 as described above. Additionally, the processor nub 18 may also provide application programming interface (API) abstractions to low-level security services provided by other hardware and may be distributed by the original equipment manufacturer (OEM) or operating system vendor (OSV) via a boot disk.

The mass storage device 170 stores archive information such as code (e.g., processor nub 18), programs, files, data, applications (e.g., applications 42₁-42_N), applets (e.g., applets 46₁ to 46_M) and operating systems. The mass storage device 170 may

include a compact disk (CD) ROM 172, a hard drive 176, or any other magnetic or optic storage devices. The mass storage device 170 also provides a mechanism to read platform-readable media. When implemented in software, the elements of the present invention are stored in a processor readable medium. The "processor readable medium" may include any medium that can store or transfer information. Examples of the processor readable medium include an electronic circuit, a semiconductor memory device, a read only memory (ROM), a flash memory, an erasable programmable ROM (EPROM), a fiber optic medium, a radio frequency (RF) link, and any platform readable media such as a floppy diskette, a CD-ROM, an optical disk, a hard disk, etc.

In communication with the platform 100, I/O devices 175 include stationary or portable user input devices, each of which performs one or more I/O functions. Examples of a stationary user input device include a keyboard, a keypad, a mouse, a trackball, a touch pad, and a stylus. Examples of a portable user input device include a handset, beeper, hand-held (e.g., personal digital assistant) or any wireless device. The I/O devices 175 enable remote attestation of the platform 100 as described below.

The token link 185 provides an interface between the ICH 150 and a fixed token 180 (e.g., a motherboard token) and/or a token reader 190 in communication with a removable token 182 having characteristics similar to a smart card. In general, both types of tokens are devices that perform dedicated I/O functions. For embodiments shown in Figures 6 and 7, tokens 180 and/or 182 include keying material (e.g., unique cryptographic identifier such as a public/private key pair) and functionality to digitally sign the audit log (or a representation thereof) with the private key of the key pair. The token link interface 158 in the ICH 150 provides a logical coupling between the token link 185 and the ICH 150 and supports remote attestation for recovery of the contents of the audit log 156.

II. Generating and Utilizing a Protected Audit Log

Referring now to Figure 2, a flowchart of the illustrative operations of the platform to generate an embodiment of the protected audit log is shown. After power-on of the platform, segments of information are loaded into the system memory for

processing by a processor (block 200). Examples of these segments of information include the processor nub and the OS nub. Concurrent with the loading of the segments of information into the system memory, copies of each segment of the information undergo a cryptographic hash operation to produce a hash value of the segments. These hash values form an audit log stored in protected memory (blocks 205 and 210). In one embodiment, as shown in Figure 1C, the protected memory is implemented within the ICH. The memory is deemed "protected" when the contents of the memory are readable and non-modifiable as described above. As subsequent segments of information are selected for storage into the audit log, their hash values are appended to the audit log behind the previously computed hash values (block 215). It is contemplated that only hash values of selected nubs may be stored in the audit log.

III. Remote Attestation

A. Commencement of Remote Attestation

In one embodiment, remote attestation is initiated by issuing an attestation request. The attestation request can originate from a remote source or from an agent, local to the platform, which may or may not be acting as a proxy for the remote source. Normally, the attestation request comprises a primary query and/or one or more optional secondary queries. Each query causes the issuance of the attestation cycles, which are designed to retrieve contents of the audit log. At a minimum, the contents of the audit log may be used to verify the integrity of IsoX™ processor and the OS nub of the platform. The secondary query retrieves, in addition to the audit log, a hash value of a selected IsoX applet loaded by the platform in order to verify the integrity of the applet. The hash value of the applet is generated on the fly by the OS nub. This avoids the need to store each and every loaded applet in the audit log. For primary queries, the RAU creates a message that may include the audit log, a digital signature covering the audit log, and one or more digital certificates for the RAU keying material and returns the message to the requestor. For secondary queries, the RAU creates a message that may include the applet hash, the audit log, a digital signature covering the applet hash and audit log, and one or more digital certificates for the RAU keying material and returns the message to the requestor to retrieve different information cited above.

B. Processor Integrated RAU

Referring now to Figure 3, the RAU 300 is integrated into the processor 110. The processor 110 is executing local code. Upon detection of an attestation request, the processor 110 establishes a communication pathway with a component 310 responsible for storing the audit log 156. More specifically, in one embodiment, the local code executes a physical instruction in response to an attestation request. The physical instruction, when executed by the processor 110, causes the issuance of attestation cycles by the processor 110 for reading contents of the audit log 156.

For illustrative sake, the component 310 may be the ICH 150 of Figure 1C, although other components within the platform 100 may be used. The communications between the processor 110 and component 310 are through one or more links such as a first link 310 and a second link 320. These links 310 and 320 may be configured as dedicated links for handling attestation cycles or shared links (e.g., host link, PCI bus, etc.) enhanced to handle the attestation cycles. These attestation cycles signal the component 310 to accept reads of the audit log 156.

Upon receiving the audit log 156, the RAU 300 in the processor 110 produces a digital signature 330 by digitally signing the audit log 156 with the keying material 340 (e.g., a pre-stored private key). The audit log 156, digital signature 330, and possibly digital certificates from the RAU keying material are packetized and sent as a message by the RAU 300 to the requestor or to an area 350 accessible to the local code.

Of course, it is contemplated that if the audit log 156 is stored in unprotected memory, the ICH 150 may include a component (not shown) to verify that the contents of the audit log 156 have not been modified before releasing the audit log 156 to the processor 110. This may be accomplished by the component 310 generating a hash value of the audit log 156 recovered from unprotected memory and comparing the hash value to the total hash value stored in protected memory.

As an optional embodiment, the user may want to control when the keying material 340 is used. For example, the platform may issue a request message via a communications device 360 to a user opt-in device 380 over a protected communication

path. In one embodiment, the communications device 360 is coupled to the token bus 185 and is employed with a wireless receiver 365 and a wireless transmitter 370 (collectively referred to herein as a "wireless transceiver"). The wireless receiver and transmitter 365 and 370 are used to establish and maintain direct communications with the user opt-in device 380. Of course, the user opt-in device 380 may be coupled to communications device 360 via any link type.

Upon receipt of the request message, the communications device 360 issues a message to the user opt-in device 380 which enables the user to affirm his or her desire to release the keying material 340 for generation of the digital signature 330. Based on an input by the user or lack thereof (e.g., depression of a key associated with user opt-in device 380, inaction by the user, etc.), a response message is returned to the communications device 360, which routes the contents of the response message to the RAU 300 over a protected communication path. Upon receipt of the response message, the RAU 300 proceeds with the generation of the digital signature 330 and/or digital certificates for the RAU keying material and placement in the area 350 accessible to the local code if use of the keying material 340 is authorized by the user.

C. Chipset Integrated RAU

Referring now to Figure 4, the RAU 300 is integrated into a core logic device 400. As shown, the processor 110 is executing local code. Upon detection of an attestation request, the core logic device 400 establishes a communication pathway with a component 420 responsible for storing the audit log 156. More specifically, in one embodiment, the local code sends a message to core logic device 400 based on an attestation request. The message causes the core logic device 400 to issue attestation cycles for reading contents of the audit log 156.

For example, in response to the attestation request, the core logic device 400 routes the attestation cycles to the component 420 via link 430 to allow contents of the stored audit log 156 to be read. Link 430 may be dedicated to support remote attestation or support multiple functions inclusive of attestation cycles generated by the core logic device 400. Upon receiving the contents of the stored audit log 156, the core logic

device 400 that contains the RAU 300 generates a digital signature 330 for the audit log 156 (as described above) and writes the digital signature 330 into an area accessible to the local code.

However, as shown in Figure 5, if the core logic device 400 also contains the audit log 156, internal signals 450 within the core logic device 400 are used to allow the RAU 300 to access the audit log 156. Again, upon receiving the contents of the audit log 156, the RAU 300 of the core logic device 400 generates the digital signature 330 of the audit log and possibly one or more digital certificates for the RAU keying material (not shown). This information is provided as a message to the requestor or written into the area accessible to the local code.

As an optional embodiment, the user may want to control when the keying material 340 is used. For example, the platform may issue a request message 470 via a communications device 460 to a user opt-in device 490 over a protected communication path. In one embodiment, the communications device 460 is coupled to the token bus 185 and is employed with a wireless transceiver 465 in order to establish and maintain direct communications with the user opt-in device 490.

In response to receiving the request message 470, the communications device 460 issues a message to the user opt-in device 490, which solicits the user to affirm his or her desire to release the keying material 340 for generation of the digital signature 330. Based on an input by the user or lack thereof (e.g., depression of a key associated with the user opt-in device 490, inaction by the user, etc.), a response message 480 is returned to the communications device 460, which routes the contents of the response message 480 to the RAU 300 of the core logic device 400 over a protected communication path. Upon receipt of the response message 480, the RAU 300 proceeds with the generation of the digital signature 330 and possibly digital certificates as described above and placement in the area accessible to the local code if use of the keying material 340 is authorized by the user.

D. Fixed Token Integrated RAU

Referring now to Figure 6, if the RAU 300 is integrated in the fixed token 180, the fixed token 180 communicates with a component (e.g., ICH 150) holding the audit log 156 over the token link 185. The functionality of token link 185 may be enhanced to support attestation cycles that are only generated by the fixed token 180 when remote attestation is being requested. These attestation cycles are routed to the ICH 150 to request acceptance of reads to the audit log 156. Upon receiving the contents of the audit log 156, the RAU 300 implemented in the fixed token 180 generates a digital signature 330 by digitally signing the audit log 156 with keying material 340 stored in the RAU 300. Thereafter, the RAU 300 writes the digital signature 330 and possibly digital certificates for keying material 340 to the requestor or into an area accessible to the local code.

As an optional embodiment, the user may want to control when the keying material 610 stored in the RAU 300 is used. For example, the user may be prompted to affirm his or her desire to release the keying material 340 for generation of the digital signature 330. The prompt may be accomplished, for example, through transmission of a message 620 via a wireless transceiver 630 situated in the token 180. Affirmation of a desire to release the keying material 340 may be made by either (1) transmitting a return message 640 from a user opt-in device to the token 180 as shown or (2) entering access information via a user opt-in device (not shown) physically connected to the token 180, for example. Thereafter, the RAU 300 proceeds with the generation of the digital signature 330 and/or digital certificate(s) for the keying material 340. Then, this information along with the audit log 156 are sent to the requestor or placed in the area accessible to the local code if use of the keying material 340 has been authorized by the user. Of course, opt-in messages 620 and 640 may be routed through the I/O device 175 provided the messages are protected.

E. Removable Token Integrated RAU

Referring now to Figure 7, if the RAU 300 is integrated in the removable token 182, the removable token 182 communicates with a component (e.g., ICH 150) holding

the audit log 156 over the token link 185. The functionality of token link 185 may be enhanced to support attestation cycles that are only generated by the token reader upon insertion or connection (i.e., wireless token) of removable token 182 when remote attestation is being requested. These attestation cycles are generated by the token reader 190 to the hardware storing the audit log 156 (e.g., ICH 150) to request acceptance of reads to the audit log 156. Upon receiving the contents of the audit log 156, the RAU 300 implemented in the removable token 182 generates the digital signature 330 by digitally signing the audit log 156 with keying material 340 stored in the RAU 300. Thereafter, the RAU 300 writes the digital signature 330 and/or digital certificate(s) for the keying material 340 into an area accessible to the local code.

As an optional embodiment, the user may want to control when the keying material 340 stored in the RAU 300 is used. For example, the user may be prompted to affirm his or her desire to release the keying material 340 for generation of the digital signature 330. The prompt may be accomplished, for example, through transmission of a message 720 via a wireless transceiver 730 situated in the token 182. Affirmation of a desire to release the keying material 340 may be made by either (1) transmitting a return message 740 from a user opt-in device (not shown) to the token 182 as shown or (2) entering access information via a user opt-in device physically connected to the token 182 (not shown) for example. Thereafter, the RAU 300 proceeds with the generation of the digital signature 330 and/or digital certificates for the keying material 340, routing through the token reader 190 and placement in the area accessible to the local code if use of the keying material 340 has been authorized by the user. Of course, opt-in messages 620 and 640 may be routed through the I/O device 175 provided the messages are protected.

While this invention has been described with reference to illustrative embodiments, this description is not intended to be construed in a limiting sense. Various modifications of the illustrative embodiments, as well as other embodiments of the invention, which are apparent to persons skilled in the art to which the invention pertains are deemed to lie within the spirit and scope of the invention.

CLAIMS

What is claimed is:

1. A platform comprising:
a processor including a remote attestation unit, the processor executing in one of a normal execution mode and an isolated execution mode;
a chipset to store an audit log; and
a link coupled to the processor and the chipset, the link to support predetermined bus cycles for the remote attestation unit to read contents of the audit log when a remote attestation request has been detected.
2. The platform of claim 1, wherein the remote attestation unit of the processor includes keying material.
3. The platform of claim 2, wherein the remote attestation unit of the processor includes a digital signature unit to digitally sign the audit log with the keying material.
4. The platform of claim 3, wherein the keying material within the remote attestation unit includes a private key.
5. The platform of claim 3, wherein the chipset includes:
a system memory including an isolated area and a non-isolated area;
a memory control hub coupled to system memory and the processor via a first link partially forming the link; and
an input/output control hub coupled to the memory control hub via a second link partially forming the link, the input/output control hub including single-write, multiple-read memory to store the audit log.

6. The platform of claim 5 further comprising a communications device coupled to the input/output control hub, the communications device enables communications with a user opt-in device.
7. The platform of claim 6, wherein the communications device includes a wireless transmitter and a wireless receiver to communicate with the user opt-in device.
8. The platform of claim 6, wherein the user opt-in device enables a user to control a stage of operation of the remote attestation by preventing the creation of the digital signature.
9. The platform of claim 2, wherein the remote attestation request includes a primary query.
10. The platform of claim 9, wherein the remote attestation unit returns a message to a requestor in response to the primary query, the message includes the audit log and at least a digital signature being the audit log digitally signed with the keying material.
11. The platform of claim 10, wherein the message further includes a digital certificate for the keying material.
12. The platform of claim 9, wherein the remote attestation request includes a secondary query.
13. The platform of claim 12, wherein the remote attestation unit returns a message to a requestor in response to the secondary query, the message includes a hash value of a selected applet, the audit log and a digital signature including the hash value and the audit log.

14. The platform of claim 13, wherein the message further includes a digital certificate for the keying material.

15. A platform comprising:
a component to contain an audit log; and
a device including a remote attestation unit to retrieve the audit log and digitally sign the audit log with keying material stored in the remote attestation unit, the audit log including representative data of software modules loaded within the platform after power-on.

16. The platform of claim 15 further comprising a processor to detect a remote attestation request and to issue cycles to the component to allow the device to access the audit log.

17. The platform of claim 15, wherein the device is a chipset.

18. The platform of claim 16 further comprising:
a chipset coupled to processor, the chipset including the component and a token link interface; and
a token link coupled to the chipset.

19. The platform of claim 15, wherein the device is a fixed token coupled to the token link.

20. The platform of claim 19, further comprising a user opt-in device in communication with the fixed token, the user opt-in device enables a user to cease operations of the remote attestation unit.

21. The platform of claim 18 further comprising a token reader coupled to the token link.

22. The platform of claim 21, wherein the device is a removable token in communication with the token reader.

23. The platform of claim 22, further comprising a user opt-in device in communication with the removable token, the user opt-in device enables a user to cease operations of the remote attestation unit.

24. A method comprising:

storing an audit log within protected memory of a platform, the audit log being a listing of data representing each of a plurality of IsoX software modules loaded into the platform;

retrieving the audit log from the protected memory in response to receiving a remote attestation request from a remotely located platform; and

digitally signing the audit log to produce a digital signature before transfer to the remotely located platform.

25. The method of claim 24, wherein the data representative of each of the plurality of software modules is a cryptographic hash value.

(54) Title: SECURE ELECTRONIC COMMERCE SYSTEM

(57) Abstract

A secure electronic commerce system and method provides for the distribution of artistic works in electronic formats. The system includes a server system which permits the author or owner of a work to upload and store an electronic copy of the work and allows a plurality of client systems to access the server system to download encrypted copies of the work. The server system can also include an electronic commerce system which enables a client system to transfer value from a credit account or a debit account to an account associated with the server system in exchange for permission to download works. The server system includes an encryption system which stores a unique key for each client system and uses the key to encrypt each work download to a corresponding client system. Each client system includes an encryption system and a unique key which enables only that system to decrypt the work to allow a consumer to use the work. The unique key can also be used to verify the identity of the client system.

BACKGROUND OF THE INVENTION

This invention relates to secure methods and systems for conducting electronic
commerce and the distribution of audio, video, and text works and, more particularly, to a
20 method and system which utilizes encryption in a client-server environment to provide
secure electronic commerce transactions and the encrypted distribution of audio, video and
text works for value.

Traditionally, entertainment and artistic works such as music and movies, are distributed by incorporating a copy of the work in a medium from which the work, such as a song or a movie, can be heard or viewed using a device. For example, music is distributed on records, tapes and compact discs and movies are distributed on tapes and digital video disks. The technologies associated with these media have developed over time in order to permit very high quality reproductions of the original work.

The technology also exists to convert these works into digital data that can be stored in memory in a computer or distributed via a network. This technology permits the works to be stored on digital media such as compact discs ("CDs") and digital video disks ("DVDs"). One of the disadvantages of this technology is that in order to provide a high level of sound and video quality, the works require very large quantities of memory. For example, a four minute song recorded on a CD occupies approximately 40 Megabytes of digital data in its native format, thus limiting the number songs that can be contained on a single CD and making distribution of music using the present network infrastructure impractical.

Alternative technologies have been developed which enable that same four minute song to be stored in less than 4 Megabytes of digital data. One such technology, MPEG 1, audio layer 3, which is more commonly known as MP3, defines how digital audio can be stored and transmitted using computers and networks. Other standards and technologies currently exist and still others are being developed.

These digital media technologies allow a consumer to store music in non-volatile memory such as a harddisk drive in a personal computer and use a software program, applet or plugin, commonly referred to as a media player, to play the music using the multimedia resources of a personal computer. Well known media players for MP3 technologies include WinAmp available from NullSoft, Inc. of Sedona, Arizona and

Sonique available from Mediascience, Inc. of San Francisco, California. These products allow a user to play MP3 encoded audio on a personal computer. Other products, such as the Rio available from Diamond Multimedia, Inc. and the MPMan available from Saehan Information Systems, Inc. of Seoul, Korea, enable a consumer to store and play MP3 encoded audio in a portable device. These electronic devices typically store the MP3 encoded audio in a flash memory that allows non-volatile storage of the audio and allows the MP3 encoded audio to be erased or over written.

Digital medial technologies such as MP3 facilitate the ability to distribute audio and video via the current network infrastructure such as the internet. These technologies enable independent authors and artists to setup websites on the World Wide Web ("WWW") to distribute their works and overcome conventional barriers to distribution, which typically require the author or artist to enter into an agreement with a third party organization, such as a publishing or recording company, to promote and distribute the author or artist's work. These technologies also provide a means for the unauthorized distribution of the work.

In addition, there is no integrated system or infrastructure in place to enable music distributors, for example, to collect royalties on a per track (or per song) basis. Presently, music is distributed in album format which includes multiple tracks. There is no effective way to track which consumers were licensed which works. There is no effective way to verify the identity of consumer who is attempting download a copy of a work over a network such as the internet.

Accordingly, it is an object of this invention to provide an improved method and system for distributing audio, video and text works.

4
It is another object of the present invention to provide an improved method and system for distributing audio, video and text works which prevents the unauthorized distribution or redistribution of the works.

It is yet another object of the present invention to provide an improved method and
5 system for managing the electronic commerce of the distribution of works and other goods or services over a network such as the internet.

SUMMARY OF THE INVENTION

The present invention is directed to a method and system for distributing goods and
10 audio, video and text works over a network, such as the Internet. The method and system according to the invention allow for the transaction to occur in a secure manner which permits the distributor to verify the identity of the consumer (or customer) and impedes the unauthorized distribution of the works by the consumer (or customer) and third parties.

15 The system according to the present invention includes a server system which permits the owner of the work or the distributor to store and distribute the work over a network and a client system which is adapted to communicate with the server system to receive copies of the work over the network. The server system can include storage memory for storing copies of the works to be distributed or alternatively the server system
20 can be adapted to access a storage facility which stores copies of the works, such as over a network or other data connection. The server system can also include an electronic commerce system which is adapted for receiving value (payment) from the consumer or customer and distributing that value to various parties for example the owner of the work and the authorized distributor of the work. The electronic commerce system can receive
25 value from the consumer on either a credit basis (such as using a credit card account) or a

debit basis (such as allowing consumers to purchase credits against which they may receive works). The server system can also include an encryption system which allows the distributor to uniquely encrypt the works distributed to a consumer. Thus, the works distributed to one consumer could be differently encrypted from the works distributed to another consumer. The server system can include an encryption key database which maintains a unique key for each consumer. The unique key can also serve to allow the distributor or retailer to verify the identity of the client system (and the consumer) and to uniquely encrypt the copy of the work or any other data that is transmitted to the client system (and the consumer).

10 The client system according to the present invention can be adapted to interface with the above described server system to transfer value from the consumer to the distributor (and the owner) and transfer a copy of the work to the consumer. The client system can include an encryption system which is uniquely adapted to decrypt the work distributed to the consumer in possession of the client system. In one embodiment, the client system can incorporate the unique key from the server system. The client system can include several unique keys from several different server systems.

The client system according to the present invention can be adapted to interface with the electronic commerce system of the above described server to facilitate the transfer of value and enable to the distributor or retailer to verify the identity of the client system and ultimately the consumer. In one embodiment, the server system maintains a unique encryption key which is embedded (or hard coded) into the client system. The server system can verify the identity of the client system by requesting the client system to transmit a predefined message, identification code, or electronic certificate which is encrypted using the key embedded in the client system. The server system can use the unique key stored in the key database to verify the encrypted message came from the

25

client that is registered in the database by decrypting the predefined message and comparing it to an expected value. The same message can include other information such as a credit card information (number and expiration date) or an authorization to debit an account (including an account number). Alternatively, other known identification
5 verification methods can be used to verify the client system.

In another embodiment, a public key encryption system can be used to encrypt the work and any messages that are transferred between the server system and to the client system. In this embodiment, the system can further include a public key server which is adapted to transmit the server system's public key to the client and the client system's
10 public key to the server system. Digital signatures can be used by both the client system and the server system to verify the identity of the other. Public key encryption systems are available from RSA Data Security, Inc. of San Mateo, California.

In one embodiment, the client system can also include a media player adapted to enable the consumer to use to the work as permitted by the owner, such as listen to an
15 audio work, view a video work or read text in a manner similar to the way one would read a book. Alternatively, a separate media player could be used. As used herein, the client system can reside on a personal computer or the client system can be a combination of hardware and software that is configured or adapted to perform the functions described, such as a portable device similar to a portable tape or CD player.

20 In an alternative embodiment of the present invention, the client and server systems can be part of a universal electronic commerce system. In this embodiment, the client system can be a universal electronic commerce client to facilitate electronic transactions over a network such as the Internet. In this embodiment, the client can be embedded into a web browser or be a "plug-in" software module that provides additional
25 functionality to a browser or other program. The universal electronic commerce system
